Entanglement Criterion for Coherent Subtraction and Coherent Addition
Bipartite Continuous variable States

Abstract
Photon subtraction and addition are experimental means of generating non-Gaussian states from Gaussian states. Coherent subtraction or addition is a combination of photon subtractions or additions. The resultant states are quite general non-Gaussian states. The states can be photon number entangled states with arbitrary coefficients. We derive the entanglement conditions for several classes of coherent subtraction or coherent addition bipartite continuous variable states. One of the entanglement conditions is necessary and sufficient.

1 Introduction
Quantum continuous variable entanglement is essential for quantum information tasks realized with quantum optical means. A great deal of contributions have been devoted to the entanglement criteria of Gaussian states which are continuous variable states that can be determined only by their first and second moments. Recently, non-Gaussian states attract much attentions for its good performance in quantum teleportation, dense coding, quantum computation and nonlocality test. Several entanglement criterion have also been proposed for non-Gaussian states. However, types of non-Gaussian states that have been studied are sporadic and limited by experimental conditions and theoretical interest until now. We will introduce the general ideas of coherent subtraction and addition to describe non-Gaussian states and study their entanglement conditions.

To generate non-Gaussian state from Gaussian state, one of the means is to subtract (or add) photon. The photon subtraction (addition) state is \( a_1^{m}a_2^{m'} \rho_G a_1^{m}a_2^{m'} \), where \( \rho_G \) is a Gaussian state (hereafter referred as Gaussian kernel), \( a_1 \) and \( a_2 \) are the annihilation operators of the two modes, \( a_1^{\dagger} \) and \( a_2^{\dagger} \) the creation operators. The replacement of \( a_i \) with the superposition \( ta_i + ra_i^{\dagger} \) has been proposed for quantum state engineering. The most generic definition of bipartite photon coherent subtraction and addition state is \( \rho_{SA} = C_{SA} \rho_G C_{SA}^{\dagger} \), where \( C_{SA} = \sum_{m_1,m_2,m_3,m_4=0}^{\infty} A_{m_1,m_2,m_3,m_4} a_1^{\dagger m_1}a_2^{\dagger m_2}a_1^{m_3}a_2^{m_4} \), with complex coefficients \( A_{m_1,m_2,m_3,m_4} \). This is so generic a definition that all two-mode continuous variable states can be expressed in such form. The photon coherent subtraction state is \( \rho_S = C_{SPC}C_{S}^{\dagger} \), with \( C_{S} = \sum_{m_1,m_2} A_{m_1,m_2} a_1^{m_1}a_2^{m_2} \). The photon coherent addition state is \( \rho_A = C_{APC}C_{A}^{\dagger} \), with \( C_{A} = \sum_{m_1,m_2} A_{m_1,m_2} a_1^{\dagger m_1}a_2^{\dagger m_2} \). More specifically, if the two modes are symmetry, the symmetric coherent subtraction and addition states are respectively.

\[
\rho_{SS} = \sum_{m=0}^{\infty} A_m a_1^{m}a_2^{m} \rho_{G} \sum_{n=0}^{\infty} A_n^{*} a_1^{\dagger n}a_2^{\dagger n},
\]

\[
\rho_{AS} = \sum_{m=0}^{\infty} A_m a_1^{m}a_2^{\dagger m} \rho_{G} \sum_{n=0}^{\infty} A_n^{*} a_1^{\dagger n}a_2^{n},
\]

respectively. The symmetric coherent subtraction or coherent addition state set is still large enough to contain many interesting non-Gaussian states. In this paper, we will study the entanglement of several symmetric coherent subtraction or addition states. Section 2 is to introduce the realignment entanglement criterion for non-Gaussian states, with a new form of the criterion in coherent state representation. Section 3 is devoted to the entanglement conditions of coherent subtraction state when the Gaussian kernel is a two-mode squeezed thermal state (TMST), when the Gaussian kernel is in its standard form. In section 4, we investigate the entanglement conditions of coherent addition states such as photon number entangled states (PNES) evolved in thermal noise and amplitude damping environment, coherent addition of TMST. Conclusions are drawn in section 5.
2 Realignment entanglement criterion in coherent state representation

The realignment entanglement criterion has been studied for continuous variable system recently [10]. The derivation is based on Fock space representation. We here give the criterion based on coherent state representation. A bipartite continuous variable state \( \rho \) is completely specified by its characteristic function \( \chi(\mu) = Tr[\rho D(\mu)] \), where \( D(\mu) = \exp(\mu a^\dagger - \mu^* a) \) is the displacement operator, and \( a = (a_1, a_2)^T, \mu = (\mu_1, \mu_2) \) for \( 1 \times 1 \) two-mode state. A Gaussian state is completely determined by its first and second moments (the first moments are not relevant). The characteristic function of a Gaussian state \( \rho_G \) with nullified first moments is \( \chi_G(\mu) = \exp(-\frac{1}{2}(\mu, \mu^*)^T \Gamma \mu) \), where \( \gamma \) is the \( 4 \times 4 \) complex covariance matrix of \( \rho_G \). Denote \( a = (a_1, a_2) \), and denote the two mode coherent state as \( |\alpha\rangle = |a_1, a_2\rangle \). In coherent state representation, we have

\[
\langle \alpha | \rho_G | \beta \rangle = \int \prod_{i=1}^2 d\mu_i \chi_G(\mu) \langle \alpha | D(-\mu) | \beta \rangle = \frac{1}{\sqrt{\det(\gamma)}} \exp\left[-\frac{1}{2}(|\alpha|^2 + |\beta|^2 - \gamma a^\dagger a/2 + (\alpha^* , \beta) \Gamma (\alpha^* , \beta)^T)\right],
\]

where \( \Gamma = Z^T \Gamma Z \), with \( Z_{11} = Z_{44} = Z_{23} = Z_{32} = 1 \) and all the other entries of the \( 4 \times 4 \) matrix \( Z \) are zeros. The realignment criterion of entanglement is \( Tr\sqrt{\rho_R \rho_R^\dagger} > 1 \), from which we can derive a condition of entanglement \( Tr\rho_R > 1 \). The later is easy for use but may detect less number of entangled states as the former. Here \( \rho_R \) is the realignment of \( \rho \). For a Gaussian state, we have the realignment entanglement sufficient condition

\[
Tr\rho_{GR} = \sqrt{\frac{\det(\gamma)}{\det(\gamma_R)}} > 1,
\]

where \( \gamma_R = \sigma_3 \otimes I_2 (\Gamma_R - \sigma_1 \otimes I_2)^{-1} \sigma_3 \otimes I_2 \).

The non-Gaussian state produced by coherent subtraction and addition from Gaussian state can be written as derivative of functional of Gaussian state. The method to derive the entanglement criterion of non-Gaussian states can be found in Ref.[10].

3 Coherent subtraction

A \( 1 \times 1 \) bipartite Gaussian state can be transformed to its first standard form (denoted as \( \rho_G^{\dagger} \)) by local operations. Further, it is always possible to transform \( \rho_G \) to its second standard form \( \rho_G^{II} \) by proper local squeezing operations[1]. To prove the necessary condition of entanglement for a Gaussian state, it is shown that a separable Gaussian state \( \rho_G^{II} \) takes the form of

\[
\rho_G^{II} = \int P(\alpha_1, \alpha_2) |\alpha_1, \alpha_2\rangle \langle \alpha_1, \alpha_2| d^2\alpha_1 d^2\alpha_2,
\]

where \( P(\alpha_1, \alpha_2) \) is a Gaussian function hence positive definite, \( |\alpha_1, \alpha_2\rangle \) is the product of coherent states.

Photon subtraction from Gaussian state \( \rho_G^{II} \) will lead to a non-Gaussian state \( a_1 a_2 \rho_G^{II} a_1^\dagger a_2^\dagger \). More generic photon subtraction is the coherent subtraction, or the superposition of all possible subtraction operations, namely, \( \sum_{m,n} A_{mn} a_1^m a_2^n \). The non-Gaussian state produced from Gaussian kernel \( \rho_G^{II} \) is

\[
\rho_S = \sum_{m,n} A_{mn} a_1^m a_2^n \rho_G^{II} \sum_{n,n'} A_{nn'} a_1^{n'} a_2^{n'}.
\]

Then state \( \rho_S \) is separable when \( \rho_G^{II} \) is separable, since we have

\[
\rho_S = \int P(\alpha_1, \alpha_2) \sum_{m,n} A_{mn} a_1^m a_2^n \langle \alpha_1, \alpha_2| d^2\alpha_1 d^2\alpha_2,
\]

which is explicitly separable. Hence a non-Gaussian state prepared by coherent subtraction from second standard form Gaussian state is separable if the kernel Gaussian state is separable. A Gaussian state with first standard form \( \rho_G^{II} \) differs from its second standard form by local squeezing, \( \rho_G^{II} = S_1(r_1)S_2(r_2) \rho_G^{II} S_1^\dagger(r_1)S_2^\dagger(r_2) \) with some properly chosen squeezing parameters \( r_1 \) and \( r_2 \), and \( S_1, S_2 \) are the single-mode squeezing operators. Keep in mind that the explicit separable decomposition [1] is only for the Gaussian state with second standard form. So \( \rho_G^{II} \) may not be diagonal in coherent state representation even when it is separable.

3.1 Coherent subtraction of two mode squeezed thermal state

A TMST is \( \rho_{st} = S(r) \rho_{th} S^\dagger(r) \), where \( S(r) = \exp[r (a_1^\dagger a_2^\dagger - a_1 a_2)] \) is the two mode squeezing operator, \( \rho_{th} = \rho_{th,1} \otimes \rho_{th,2} \) is the thermal state with \( \rho_{th,i} = (1-v_i) \sum_n v_i^* |n\rangle \langle n| \). The average photon number of state \( \rho_{th,i} \) is \( N_i = v_i/(1-v_i) \). Consider the case of symmetric modes, we have \( N_1 = N_2 = N \). The characteristic function of \( \rho_{st} \) is
\( \chi_{\mu}(\mu) = \exp[-\frac{1}{2}(\mu, \mu^*)^T], \) where the complex covariance matrix \( \gamma = b_0 \sigma_1 \otimes I_2 + c_1 I_2 \otimes \sigma_1, \) with \( b_0 = (N + \frac{i}{2}) \cosh 2r, \) \( c_1 = -(N + \frac{i}{2}) \sinh 2r. \) The characteristic function can also be written as \( \chi(\mu_1, \mu_2) = \exp[-\frac{1}{2}(\mu_1^T \rho_1^R, \mu_2^T \rho_2^R)M(\mu_1^T \rho_1^R, \mu_2^T \rho_2^R)^T], \) where \( \mu_1^T \rho_1^R \) and \( \mu_2^T \rho_2^R \) are imaginary and real parts of \( \mu_i. \) The real symmetric correlation matrix is \( M = 2b_0 I_2 \otimes I_2 - 2c_1 \sigma_1 \otimes \sigma_3. \) Notice that \( \chi \) is separable if and only if \( \tau = \frac{1}{4(b_0 + c_1)} > 1. \) For symmetric coherent subtraction state \( \rho_{SS} = \sum_m A_m a_{m}^\dagger a_{m}^\dagger \rho_G \sum_n A_n^* a_{n}^\dagger a_{n}^\dagger, \) we consider if it is separable at the \( \tau = 1 \) and \( c_2 \neq 0, \) the boundary of separability of its Gaussian kernel. The entanglement criterion is

\[
\mathcal{O}^R > \mathcal{O}_g, \tag{6}
\]

where \( \mathcal{O}_g = \exp[b(\eta_1\xi_2 + \xi_1\eta_2) - c_1(\eta_1\xi_1 + \eta_2\xi_2) + c_2(\eta_1\xi_2 + \eta_2\xi_1)], P = \exp[-c_1(\eta_1\xi_2 + \xi_1\eta_2) + \xi_2(\eta_1\eta_2 + \eta_1\xi_2) + \xi_2(\eta_1\xi_2 + \eta_2\xi_1)], \) with \( b = b_0 - \frac{i}{2}. \) Then

\[
\mathcal{O}_g = \sum_{m,n} m!n! A_m A_n^* \sum_{k=0}^{\min(m,n)} \binom{m}{k} \binom{n}{k} c_2^{2k} \sum_{l=0}^{\min(m,n)-k} \binom{m-k}{l} \binom{n-k}{l} b^{n+m-2l-2} \epsilon_1^2. \]

The same expression can be found for \( \mathcal{O} \) with the interchange of \( b \) and \( -c_1. \) Consider the function \( f_{m'n'}(x) = \sum_{x'=0}^{\min(m',n')} \binom{m'}{l} \binom{n'}{l} (x^{l} - x'^{l}) \). Notice that \( f_{m'n'}(x) = 0, \) we only need to consider \( m' \neq n'. \) For odd \( m' + n', \) one of the roots for equation \( f_{m'n'}(x) = 0 \) is \( x = 1; \) for even \( m' + n', \) \( x = \pm 1 \) are the roots of equation \( f_{m'n'}(x) = 0. \) We have verified numerically that there are no other real roots for all \( m', \) \( n' \leq 200. \) Since \( f_{m'n'}(0) = 0, \) we have \( f_{m'n'}(x) > 0 \) for all \( x \in (-1,1). \) From \( \tau = 1, \) we have \( b + c_1 = \sqrt{\epsilon_2^2 + \frac{1}{4}} > 0, \) thus \( -\frac{c_1}{b} \in (0,1) \) as \( c_1 \) is assumed to be negative (for positive \( c_1, \) the realignment criterion \( TR^R > 1 \) should be modified \( 16), \) then \( f_{m'n'}(-\frac{c_1}{b}) > 0. \) At \( \tau = 1, \) the realignment entanglement criterion \( \mathcal{O}^R > \mathcal{O}_g > 0 \) can be rewritten as

\[
\sum_{m,n} B_{mn} \min_{k=0}^{\min(m,n)} \binom{m}{k} \binom{n}{k} c_2^{2k} b^{n+m-2k} f_{m-k,n-k} (-\frac{c_1}{b}) > 0, \tag{7}
\]

where

\[
B_{mn} = m! n! (A_m A_n^* + A_n A_m^*). \tag{8}
\]

If \( B_{mn} > 0 \) for all \( m, n \) and \( B_{mn} > 0 \) at least for one pair of \( m, n \) \( (m \neq n), \) the coherent subtracted state \( \rho_{SS} \) is completely characterized by its complex covariance matrix \( \gamma = b_0 \sigma_1 \otimes I_2 + c_1 I_2 \otimes \sigma_1, \) with \( b_0 = Tr[\rho_G(a_{1}^\dagger a_{1}^\dagger)] = Tr[\rho_G(a_{2}^\dagger a_{2}^\dagger)], \) \( c_1 = Tr[\rho_G a_{1} a_{2}], \) \( c_2 = Tr[\rho_G a_{2} a_{1}]. \) The real symmetric correlation matrix is \( M^l = 2b_0 I_2 \otimes I_2 - 2c_1 \sigma_1 \otimes \sigma_3 + 2c_2 \sigma_1 \otimes I_2. \) The necessary and sufficient condition of the entanglement of \( \rho_G^l \) is

\[
\frac{1}{4(b_0 + c_1)} > 1. \]

3.2 Symmetric coherent subtraction of standard form Gaussian state

The first standard form Gaussian state \( \rho_G^l \) is completely characterized by its complex covariance matrix \( \gamma = b_0 \sigma_1 \otimes I_2 + c_1 I_2 \otimes \sigma_1, \) where \( b_0 = Tr[\rho_G(a_{1}^\dagger a_{1}^\dagger)] = Tr[\rho_G(a_{2}^\dagger a_{2}^\dagger)], \) \( c_1 = Tr[\rho_G a_{1} a_{2}], \) \( c_2 = Tr[\rho_G a_{2} a_{1}]. \) The real symmetric correlation matrix is \( M^l = 2b_0 I_2 \otimes I_2 - 2c_1 \sigma_1 \otimes \sigma_3 + 2c_2 \sigma_1 \otimes I_2. \) The necessary and sufficient condition of the entanglement of \( \rho_G^l \) is
4 Coherent addition

Unlike the coherent subtraction state, the sufficient condition of separability for a coherent addition state is difficult to be found even when the Gaussian kernel $\rho_G$ is in its second standard form. We will consider the sufficient condition of entanglement for symmetric coherent addition state $\rho_{SA} = \sum_{m,n} A_m A_n' |m\rangle \langle n| \rho_G \sum_{n} A_n a_n' a_n^2$ in the following. An initially prepared non-Gaussian entangled state will become separable after it interact with the thermal noise and amplitude damping environment. The evolution of the state could be specified by the evolution of its characteristic function [13]. The realignment entanglement criterion for time evolution state is [10]

$$\sqrt{\frac{\text{det}(\gamma_{ni})}{\text{det}(\gamma_i)}} \mathcal{O} \exp[-\frac{1}{2} \mathbf{v} \Omega \mathbf{v}^T] > \mathcal{O} \exp[-\frac{1}{2} \mathbf{v} \gamma' \mathbf{v}^T].$$

(9)

where $\mathbf{v} = (z_1, z_2, -\zeta_1, -\zeta_2), \mathcal{O} = \sum_{m,n} A_m A_n^2 \mathcal{O}_{mn}$, with $\mathcal{O}_{mn} = \frac{\gamma_2^{m+n+2}}{\gamma_2^{m+n}} |t_{\xi,\zeta_1,\zeta_2}^{m+n} \rangle \langle t_{\xi,\zeta_1,\zeta_2}^{m+n}|$, $\gamma_i = \gamma_1 + e^{-t} \gamma_1' (-\gamma_1' + \gamma_1' Z_1^\dagger Z_1' t_{\xi,\zeta_1,\zeta_2}^{m+n} \rangle \langle t_{\xi,\zeta_1,\zeta_2}^{m+n}|$$ with $\gamma_{ni} = e^{-t} \gamma_1 + (\tilde{n} + 1)(1 - e^{-t}) \sigma_1 \otimes I_2, \gamma_{ni}' = (Z_1' t_{\xi,\zeta_1,\zeta_2}^{m+n} \rangle \langle t_{\xi,\zeta_1,\zeta_2}^{m+n}| \sigma_2 \otimes I_2)^{-1}$ and $Z' = (\sigma_3 \otimes I_2) Z (\sigma_3 \otimes I_2)$. Here $\tilde{n}$ is the thermal noise, the amplitude damping coefficient is merged in the unit of time $t$.

4.1 Photon number entangled state

A special case of symmetric coherent addition state is the PNES when the Gaussian kernel $\rho_G$ is the vacuum state. We have $\rho_{PNES} = |\psi\rangle \langle \psi|$ where $|\psi\rangle = \sum_{m=0}^{\infty} m A_m |m\rangle |m\rangle$. For vacuum Gaussian kernel, $\gamma' = \sigma_1 \otimes I_2, \gamma_{ni} = n \sigma_1 \otimes I_2, \gamma_{ni}' = (2n - 1)! [1-n(t_{\xi,\zeta_1,\zeta_2}^{m+n} \rangle \langle t_{\xi,\zeta_1,\zeta_2}^{m+n}| \sigma_2 \otimes I_2)^{-1}$, where $n_t = \tilde{n}(1 - e^{-t}) + 1$. Then $\Omega = -z t_{\xi,\zeta_1,\zeta_2}^{m+n} \rangle \langle t_{\xi,\zeta_1,\zeta_2}^{m+n}| (1 - z) \sigma_3 \otimes I_2$, with $z = e^{-t} / (2n_t - 1) = e^{-t} / [2n_t(1 - e^{-t}) + 1]$. Denote $F = -\frac{1}{2} \mathbf{v} \Omega \mathbf{v}^T = z (\varepsilon_1 \varepsilon_2 + \zeta_1 \zeta_2) + (1 - z) (\varepsilon_1 \zeta_1 + \varepsilon_2 \zeta_2)$, then

$$\mathcal{O}_{mn} e^{F} = \frac{1}{(m+n)!} \mathcal{O}_{mn} F^{m+n} = m! n! \sum_{k=0}^{\text{min}(m,n)} \binom{m}{k} \binom{n}{k} (1-z)^{2k} z^{n+m-2k}.$$  

We also get $\mathcal{O}_{mn} \exp[-\frac{1}{2} \mathbf{v} \gamma' \mathbf{v}^T] = m! n! \delta_{mn}, \sqrt{\frac{\text{det}(\gamma_{ni})}{\text{det}(\gamma_i)}} = \frac{1}{m! n!}$. The realignment entanglement criterion for time evolution PNES is

$$\sum_{n,m} C_m C_n e^{\sum_{k=0}^{\text{min}(m,n)} \binom{m}{k} \binom{n-k}{k} (1-z)^{2k} z^{n+m-2k} > 1.$$  

(10)

where $C_m = \frac{m! A_m}{\sqrt{\sum_{n=0}^{\infty} n! A_n}}$.

Figure 1: (a) The critical damping time of separability for TMC, $N$ is the average energy of input state, it is a bit less than $\lambda$. From up to bottom, the thermal noise $\tilde{n} = 10^{-5}, 10^{-4}, 10^{-3}, 10^{-2}, 10^{-1}$, respectively. (b) The critical damping time of separability for photonic Bell-state. The solid line is the realignment criterion, the dash line is the Simon’s criterion.

For a two mode squeezed thermal state evolving in amplitude damping and thermal noise channel, the initial state is $|\psi\rangle = \sqrt{1-x^2} \sum_{m=0}^{\infty} \lambda^m |m\rangle |m\rangle$, thus $C_m = \sqrt{1-x^2} \lambda^m$. By interchanging the order of summations in [10], the entanglement criterion of the final state reduces to

$$\frac{1 + \lambda}{(2n_t - 1)(1 + \lambda - 2\lambda z)} > 1.$$  

(11)

Condition (11) can also be derived from the well known entanglement condition of Gaussian state, for the final state is Gaussian. This example shows that the choice of Gaussian kernel may not be relevant for the entanglement criterion.

For a two mode coherently correlated state (TMC) with Poisson coefficients evolves in thermal noise and amplitude damping channel, the unnormalized initial state is $|\psi\rangle = \sum_{m=0}^{\infty} \lambda^m |m\rangle |m\rangle$, then $C_m = \lambda^m / g(\lambda)m!$, where $g(x) = \sum_{m=0}^{\infty} (\frac{x}{m!})^2$. The function $g(x)$ converges fast than exponential function. The entanglement criterion [10] leads to

$$e^{2\lambda z} g(\lambda(1 - z)) > (2n_t - 1)g(\lambda).$$  

(12)

The critical separable time is shown in Fig.1(a) for different noise $\tilde{n}$. Comparing with the direct numerical calculation [17], we confirm that the numerical calculation of the realignment entanglement criterion of TMC is valid.

Another example is the evolution of photonic Bell-state $|\Psi_B\rangle = c_0 |00\rangle + c_1 |11\rangle$ in thermal noise and amplitude damping environment. The entanglement criterion [10] leads to

$$|c_0|^2 + 2Re(c_0 c_1^*) z + |c_1|^2 (1 - 2z + 2z^2) > 2n_t - 1.\quad(13)$$

The critical separable time is shown in Fig.1(b), where the Simon’s criterion is also shown for comparison [2]. The similar curve has been obtained by Nha’s criterion[14].
The coherent addition of symmetric TMST is
\[
\rho_{AS} = \sum_{m=0}^{\infty} A_m a_1^m a_2^m \rho_{st}\sum_{n=0}^{\infty} A_n^* a_1^m a_2^m.
\]
The re-alignment entanglement criterion is still \(O\), where
\[
O = \sum_{m,n} A_m A_n^* \Omega = \frac{1}{2}((b_0 - c_1) - (b_0 + c_1)\sigma_1 \otimes I_2 - \frac{1}{2}((b_0 + c_1)\tau + (b_0 - c_1) + 1)I_2 \otimes \sigma_1, \]
\[
\Omega = -c_1\sigma_1 \otimes I_2 - (b_0 + \frac{1}{2})I_2 \otimes \sigma_1.
\]
The entanglement criterion then reads
\[
\sum_{m>n} B_{mn}(b_0 + \frac{1}{2})^{n+m} f_{m,n}(-\frac{c_1}{b_0 + \frac{1}{2}}) > 0,
\]
where \(B_{mn}\) is defined as in [5]. Notice that when \(\tau = 1\), we have
\[
\frac{c_1}{b_0 + \frac{1}{2}} = \frac{-c_1}{-c_1 + 1} \in (0,1), \text{ here } c_1 < 0 \text{ is assumed}
\]
as before. Hence \(f_{m,n}(-\frac{c_1}{b_0 + \frac{1}{2}}) > 0\) as we have argued. So if all \(B_{mn}\) are nonnegative (at least one of them is nonzero thus it is positive), the state should be entangled. One of the cases is that if only two of the coefficients are nonzero, say \(A_m\) and \(A_n\), the entanglement condition will be
\[
A_m A_n^* + A_n A_m^* > 0.
\]
Denote \(A_m = |A_m| e^{i\varphi_m}\), the entanglement condition reduces to
\[
\cos(\varphi_m - \varphi_n) > 0.
\]
for any \(m \neq n\). Thus if the argument difference of the two complex coefficients is an acute angle, the state is entangled. Borrowing term from optics, we can say that if the coherent addition constructively interferes, the state is entangled.

5 Conclusions

We have introduced the ideas of coherent subtraction and coherent addition to describe many kinds of bipartite non-Gaussian states and investigate their inseparability. The non-Gaussian states produced from their Gaussian kernels are quite generic. The results of the paper are of several folds. For any coherent subtraction state produced form the second standard form [1] Gaussian state, we prove that it is always separable when the Gaussian kernel is separable. For any symmetric coherent subtraction state produced from the symmetric two-mode squeezed thermal state, the necessary and sufficient separable condition is obtained and it is exactly the same as that of its kernel state. A symmetric coherent subtraction state produced from the symmetric first standard form Gaussian state (except two-mode squeezed thermal state) is entangled when the Gaussian kernel is at the boundary of separability and all the superposition coefficients have positive real and/or imaginary parts. Thus a proper arranged coherent subtraction produces entanglement from a separable state. For photon number entangled state evolving in thermal noise and amplitude damping channel, we give the analytical entanglement condition. As applications, we present the separable conditions of two mode coherently correlated states with Poisson coefficients and photonic Bell states evolving in thermal noise and amplitude damping environment. Any two term coherent addition state produced form boundary separable symmetric two-mode squeezed thermal state is entangled if the two complex coefficients give rise to constructive interference. Further works are desirable for other non-Gaussian states or using entanglement criterion other than realignment criterion.
